

# Objectives

## Tail Recursion

Dr. Mattox Beckman

UNIVERSITY OF ILLINOIS AT URBANA-CHAMPAIGN  
DEPARTMENT OF COMPUTER SCIENCE

- ▶ Identify expressions that have subexpressions in tail position.
- ▶ Explain the tail call optimization.
- ▶ Convert a direct style recursive function into an equivalent tail recursive function.

## Tail Calls

**Tail Position** A subexpression  $s$  of expressions  $e$ , if it is evaluated, will be taken as the value of  $e$ . Consider this code:

- ▶ if  $x > 3$  then  $\underline{x + 2}$  else  $\underline{x - 4}$
- ▶  $f(x * 3)$  – no (proper) tail position here

**Tail Call** A function call that occurs in tail position

- ▶ if  $h\ x$  then  $\underline{h\ x}$  else  $x + g\ x$

## Your Turn

Find the tail calls!

### Example Code

```
1 fact1 0 = 1
2 fact1 n = n * fact1 (n-1)
3
4 fact2 n = aux n 1
5   where aux 0 a = a
6         aux n a = aux (n-1) (a*n)
7
8 fib 0 = 0
9 fib 1 = 1
10 fib n = fib (n-1) + fib (n-2)
```

### Tail Call Example

- ▶ If one function calls another in tail position, we get a special behavior.

#### Example

```

1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
    
```

- ▶ What happens when we call foo 1?

### Tail Call Example

- ▶ If one function calls another in tail position, we get a special behavior.

#### Example

```

1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
    
```

- ▶ What happens when we call foo 1?

### Tail Call Example

- ▶ If one function calls another in tail position, we get a special behavior.

#### Example

```

1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
    
```

- ▶ What happens when we call foo 1?

### Tail Call Example

- ▶ If one function calls another in tail position, we get a special behavior.

#### Example

```

1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
    
```

- ▶ What happens when we call foo 1?

### Tail Call Example

► If one function calls another in tail position, we get a special behavior.

#### Example

```
1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
```

► What happens when we call foo 1?

### Tail Call Example

► If one function calls another in tail position, we get a special behavior.

#### Example

```
1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
```

► What happens when we call foo 1?

### Tail Call Example

► If one function calls another in tail position, we get a special behavior.

#### Example

```
1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
```

► What happens when we call foo 1?

### Tail Call Example

► If one function calls another in tail position, we get a special behavior.

#### Example

```
1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
```

► What happens when we call foo 1?

## Tail Call Example

- ▶ If one function calls another in tail position, we get a special behavior.

### Example

```

1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
    
```

- ▶ What happens when we call foo 1?

## The Tail Call Optimization

### Example

```

1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
    
```

- ▶ If that's the case, we can cut out the middle man ...

## The Tail Call Optimization

### Example

```

1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
    
```

- ▶ If that's the case, we can cut out the middle man ...

## The Tail Call Optimization

### Example

```

1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
    
```

- ▶ If that's the case, we can cut out the middle man ...

# The Tail Call Optimization

## Example

```

1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
    
```

► If that's the case, we can cut out the middle man ...

# The Tail Call Optimization

## Example

```

1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
    
```

► If that's the case, we can cut out the middle man ...

# The Tail Call Optimization

## Example

```

1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
    
```

► If that's the case, we can cut out the middle man ...

# The Tail Call Optimization

## Example

```

1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
    
```

- If that's the case, we can cut out the middle man ...
- Actually, we can do even better than that.

# The Optimization

▶ When a function is in tail position, the compiler will *recycle the activation record!*

## Example

```
1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
```

# The Optimization

▶ When a function is in tail position, the compiler will *recycle the activation record!*

## Example

```
1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
```

# The Optimization

▶ When a function is in tail position, the compiler will *recycle the activation record!*

## Example

```
1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
```

# The Optimization

▶ When a function is in tail position, the compiler will *recycle the activation record!*

## Example

```
1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
```

## The Optimization

- ▶ When a function is in tail position, the compiler will *recycle the activation record!*

### Example

```
1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
```

## The Optimization

- ▶ When a function is in tail position, the compiler will *recycle the activation record!*

### Example

```
1 foo x = bar (x+1)
2 bar y = baz (y+1)
3 baz z = z * 10
```

- ▶ This allows recursive functions to be written as loops internally.

## Direct-Style Recursion

- ▶ In recursion, you split the input into the "first piece" and the "rest of the input."
- ▶ In direct-style recursion: the recursive call computes the result for the rest of the input, and then the function combines the result with the first piece.
- ▶ In other words, you wait until the recursive call is done to generate your result.

### Direct Style Summation

```
1 sum [] = 0
2 sum (x:xs) = x + sum xs
```

## Accumulating Recursion

- ▶ In accumulating recursion: generate an intermediate result *now*, and give that to the recursive call.
- ▶ Usually this requires an auxiliary function.

### Tail Recursive Summation

```
1 sum xs = aux xs 0
2   where aux [] a = a
3         aux (x:xs) a = aux xs (a+x)
```

### Convert These Functions!

► Here are three functions. Try converting them to tail recursion.

```

1 fun1 [] = 0
2 fun1 (x:xs) | even x = fun1 xs - 1
3             | odd x  = fun1 xs + 1
4
5 fun2 1 = 0
6 fun2 n = 1 + fun2 (n `div` 2)
7
8 fun3 1 = 1
9 fun3 2 = 1
10 fun3 n = fun3 (n-1) + fun3 (n-2)

```

### Solution for fun1 and fun2

► Usually it's best to create a local auxiliary function.

```

1 fun1 xx = aux xx 0
2   where aux [] a = a
3         aux (x:xs) | even x = aux xs (a-1)
4                   | odd x  = aux xs (a+1)
5
6 fun2 n = aux n 1
7   where aux 1 a = a
8         aux n a = aux (n `div` 2) (a+1)

```

### Solution for fun3

► Because the recursion calls itself twice, we need two accumulators.

```

1 fun3 n = aux n 1 1
2   where aux 0 f1 f2 = f1
3         aux n f1 f2 = aux (n-1) f2 (f1+f2)

```
